

## WHAT ARE THE ECONOMIC BENEFITS OF EDUCATION?

This indicator examines the relative earnings of workers with different levels of educational attainment of 25 OECD countries and the partner economy Israel. This indicator also presents data that describe the distribution of pre-tax earnings (see Annex 3 for notes) within five ISCED levels of educational attainment to help show how returns to education vary within countries among individuals with comparable levels of educational attainment. The financial returns to educational attainment are calculated for investments undertaken as a part of initial education, as well as for the case of a hypothetical 40-year-old who decides to return to education in mid-career. For the first time, this indicator presents new estimates of the rate of return for an individual investing in upper secondary education instead of working for the minimum wage with a lower secondary level of education.

### Key results

**Chart A9.1. Private internal rates of return for an individual obtaining an upper secondary or post-secondary non-tertiary education, ISCED 3/4 and for an individual obtaining a university-level degree, ISCED 5/6 (2003)**

- Private internal rates of return for an individual immediately acquiring the next level of education: an upper secondary or post-secondary non-tertiary education, ISCED 3/4
- ▲ Private internal rates of return for an individual immediately acquiring the next level of education: a tertiary level degree, ISCED 5/6

In all countries, for males and females, private internal rates of return exceed 4.5% on an investment in upper secondary education (completed immediately following initial education). Private internal rates of return are, on average, higher for investment in upper secondary or post-secondary non-tertiary education than for tertiary education. Attaining higher levels of education can be viewed as an economic investment in which there are costs paid by the individual (including reductions in earnings while receiving education) that typically result in higher earnings over the individual's lifetime. In this context, the investment in obtaining a tertiary degree, when undertaken as part of initial education, can produce private annual returns as high as 22.6%, with all countries showing a rate of return above 8%.

### *Other highlights of this indicator*

- Earnings increase with each level of education. Those who have attained upper secondary, post-secondary non-tertiary or tertiary education enjoy substantial earnings advantages compared with those of the same gender who have not completed upper secondary education. Across all countries, individuals with tertiary-type A and advanced research education had earnings that were at least 50% higher than individuals whose highest level of educational attainment was below upper secondary level of education (Chart A9.4).
- In all countries, females earn less than males with similar levels of educational attainment (Table A9.3). For a given level of educational attainment, they typically earn between 50 and 80% of what males earn.
- Countries differ significantly in the dispersion of earnings among individuals with similar levels of educational attainment. Although individuals with higher levels of education are more likely to be in the highest earnings group, this is not always the case. The proportion of individuals with the highest educational attainment (tertiary-type A and advanced research programmes) in the lowest earning category (at or below half of the median) vary from 0 to 19.6%, in Portugal and Canada, respectively. Countries also differ in the relative share of men and women in the upper and lower categories of earnings.
- In all countries, it is profitable for a 40-year-old to return to education mid-career and obtain a tertiary degree. This applies to both males and females. The rate of return when the individual, at age 40, begins the next level of higher education in full-time university studies varies between 6.5% for males in New Zealand and 28.2% for females in Belgium.

## Policy context

One way in which markets provide incentives for individuals to develop and maintain appropriate skills is through wage differentials – in particular through the enhanced earnings awarded to persons with higher levels of education. At the same time, education involves costs that must be balanced against these higher earnings. This indicator examines relative earnings associated with different levels of education, the variation in these earnings and the estimated rates of return to individuals making investments to obtain higher levels of education.

The dispersion of earnings is also relevant for policies that support attainment of higher levels of education. Evidence suggests that some individuals may be receiving relatively low returns to investments in education, that is, they earn relatively low wages even though they have relatively high levels of educational attainment. Policy makers may wish to examine characteristics of the education programmes which appear to have low rates of return for some people or to examine the characteristics of the individuals in these programmes, such as their gender or occupation.

## Evidence and explanations

### Education and earnings

#### *Earnings differentials according to educational attainment*

A key measure of the financial incentive available for an individual to invest in further education, earnings differentials may also reflect differences in the supply of educational programmes at different levels (or barriers to access to those programmes). The earnings benefit of completing tertiary education can be seen by comparing the average annual earnings of those who graduate from tertiary education with the average annual earnings of upper secondary or post-secondary non-tertiary graduates. The earnings disadvantage from not completing upper secondary education is apparent from a similar comparison of average earnings. Variations in relative earnings (before taxes) among countries reflect a number of factors, including the demand for skills in the labour market, minimum wage legislation, the strength of unions, the coverage of collective bargaining agreements, the supply of workers at the various levels of educational attainment, the range of work experience of workers with high and low levels of educational attainment, the distribution of employment among occupations and, last but not least, the relative incidence of part-time and seasonal work.

Chart A9.2 shows a strong positive relationship between educational attainment and average earnings. In all countries, graduates of tertiary-level education earn substantially more than upper secondary and post-secondary non-tertiary graduates. Earnings differentials between those who have tertiary education – especially those with a tertiary-type A level of attainment – and those who have upper secondary education are generally more pronounced than the differentials between upper secondary and lower secondary or below, suggesting that in many countries upper secondary (and, with a small number of exceptions, post-secondary non-tertiary) education forms a break-point beyond which additional education attracts a particularly high premium. Table A9.1a shows that the earnings premium for 25-to-64-year-olds with tertiary-level education, relative to upper secondary education, ranges from 26% in Denmark (2004) to 115% in Hungary (2005).

The earnings data shown in this indicator differ across countries in a number of ways. The results should therefore be interpreted with caution. In particular, in countries reporting annual earnings, differences in the incidence of seasonal work among individuals with different levels of educational attainment will have an effect on relative earnings that is not reflected in the data for countries reporting weekly or monthly earnings (see the Definitions and methodologies section below).

A9

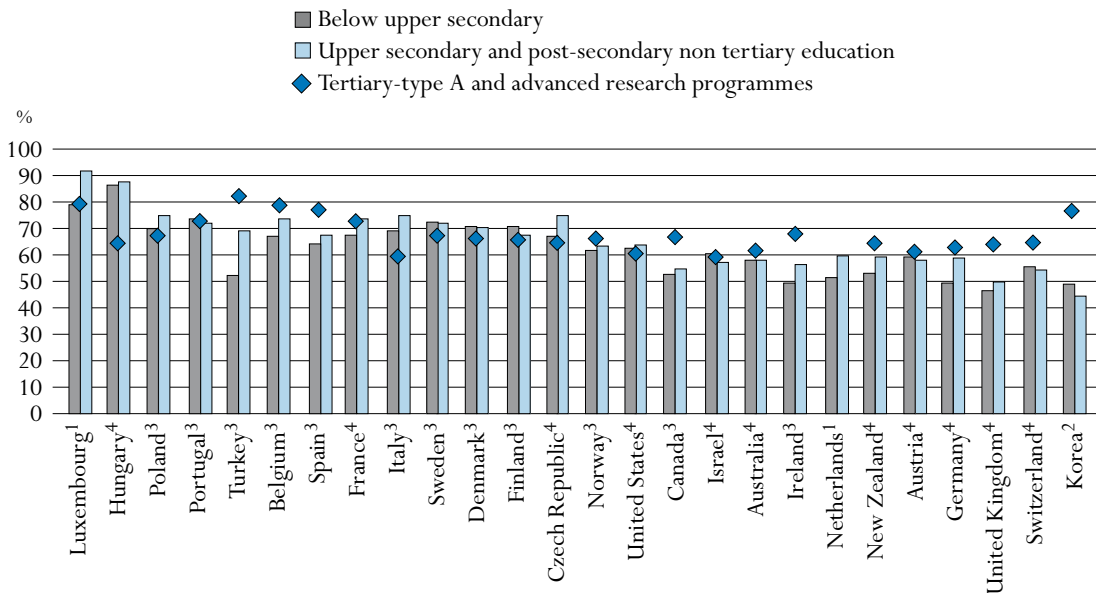

Education and gender disparity in earnings

For 25-to-64-year-olds, financial rewards from tertiary education benefit females more than males in Australia, Austria, Canada, Ireland, Korea, the Netherlands, Norway, Spain, Switzerland, Turkey and the United Kingdom. The reverse is true in the remaining countries, with the exception of Belgium and Germany, where – relative to upper secondary education – the earnings of males and females are equally enhanced by tertiary education (Table A9.1a).

Both males and females with upper secondary, post-secondary non-tertiary or tertiary attainment have substantial earnings advantages (compared with those of the same gender who do not complete upper secondary education), but earnings differentials between males and females with the same educational attainment remain substantial. In all countries, and at all levels of educational attainment, females in the 30-to-44-year-old age group earn less than their male counterparts (Chart A9.3 and Table A9.1b). When all levels of education are taken together (i.e. total earnings are divided by the total number of income earners, by gender), average earnings of females between the ages of 30 and 44 range from 51% of those of males, in Korea, to 84% in Luxembourg (Chart A9.3 and Table A9.1b).

**Chart A9.3. Differences in earnings between females and males (2005 or latest available year)**

Notes: Data on earnings for individuals in part-time work are excluded for the Czech Republic, Hungary, Luxembourg and Poland, while data on part-year earnings are excluded for Hungary, Luxembourg and Poland.

Source: OECD. Table A9.1b. See Annex 3 for notes ([www.oecd.org/edu/eag2007](http://www.oecd.org/edu/eag2007)).

StatLink <http://dx.doi.org/10.1787/068170623457>

The relative differential between men and women must be treated with caution, however, since in most countries earnings data include part-time work. Part-time work is often a major characteristic of women's employment and its prevalence is likely to vary a lot from one country to another. In Luxembourg, Hungary and Poland, those with part-time work and part-year earnings are excluded from the calculations. Earnings of females between the ages of 30 and 44 reach 84, 83 and 81% of those of males, respectively.

The gap in earnings between males and females presented in Chart A9.3 is explained in part by different choices of career and occupation, differences in the amount of time that males and females spend in the labour force, and the relatively high incidence of part-time work among females.

### *The distribution of earnings within levels of educational attainment*

Data on the distribution of the share of individuals with a given level of educational attainment in different earnings groups can be used to describe how tightly earnings are distributed around the country median.

Tables A9.4a, A9.4b and A9.4c show the distributions of earnings among 25-to-64-year-olds for 25 OECD countries and the partner economy Israel. Distributions are given for the combined male and female populations, as well as for males and females separately. There are five categories of the earnings distribution, ranging from "At or below one-half of the median" to "More than twice the median". For example, in Table A9.4a, for Australia, the figure of 24.3% is found in the row "Below upper secondary" under the column "At or below one-half of the median". This means that 24.3% of Australians who are between the ages of 25 and 64 and whose highest educational attainment is below the upper secondary level have pre-tax earnings at or below one-half of the median earnings of all Australian 25-to-64-year-olds who had earnings from work during the reference period of the national survey. Tables A9.4b and A9.4c also present earnings distributions among males and females relative to the median of the entire adult population with earnings from work.

Indicators based on average earnings do not consider the range of earnings that individuals with a given level of educational attainment experience. Some individuals with high levels of educational attainment may have relatively low levels of earnings and individuals with low levels of education may have high levels of earnings. This variation may reflect differences in the returns to education across individuals and may be of concern to policy makers if they indicate that the labour market signals individuals receive as they consider investment in education are not clear.

The data show that in most countries the share of individuals in the lowest earnings categories falls as the level of educational attainment rises. This result is another way of viewing the well-established positive relationship between earnings and educational attainment. However, it is notable that even at higher levels of education there are individuals in the lower earnings categories, indicating that they have experienced a relatively low rate of return to education.

Still, countries differ significantly in the dispersion of earnings. For instance, Table A9.4a shows that in most countries the largest proportion of the population has earnings above one-half of the median but less than 1.5 times the median. Yet this percentage ranges from less than 45% in

Canada to more than 80% in Belgium. Across all levels of education, countries such as Belgium, the Czech Republic, Luxembourg and Portugal have no or relatively few individuals with earnings either at or below one-half the median. Conversely, while across all countries almost 22%, on average, of individuals between the ages of 25 and 64 have earnings above 1.5 times the median, this population share is as low as 14.1% in Belgium.

Countries also differ significantly in the gender distribution of individuals in the lowest earnings group. For example, taking into account all levels of educational attainment, Hungary is the only country in which the percentage of females in the lowest earnings category is smaller than the percentage of males in the same category. At the opposite end of the spectrum, the percentage of females in the highest earnings category is smaller than that of males in all countries. This is particularly marked in Switzerland, with 13% of males in the highest earnings category versus 2% of females and 4% of males in the lowest earnings category compared to 35% of females (Chart A9.5).

### *The interpretation of earnings dispersion data*

A wide range of factors – from differences in institutional arrangements to variation in individual abilities – is likely to determine the extent of earnings dispersion among individuals of similar educational attainment. At an institutional level, countries in which wage setting is more centralised would tend to see lower earnings dispersion, owing to a degree of convergence between occupational status and educational attainment. More broadly, earnings dispersions also reflect the fact that educational attainment cannot be fully equated with proficiency and skills: skills other than those indicated by educational attainment, as well as experience, are rewarded in the labour market. Differences in the scale and operation of training systems for adult learners also influence national patterns of earnings dispersion, as do non-skills-related recruitment considerations – such as gender, race or age discrimination (and consequently the relative effectiveness of national legislative frameworks in countering such problems). Finally, note that in Belgium earnings are centred on the median; this is probably in part because Belgian earnings data are net of income tax.

However, the data do show that in all countries, earnings dispersion falls as educational attainment rises. This trend has many possible interpretations, including that greater educational attainment could be providing more information on an individual's skills to potential employers, resulting in a closer link between education and wages.

More generally, the data point to gaps in the understanding of earnings determination. Research in the United States has shown that for individuals of the same race and sex, over one-half of the variance in earnings is not explained by quantifiable factors such as a person's years of schooling, age, duration of labour market experience, or indeed the schooling, occupation and income of their parents. Some research on the determinants of earnings has highlighted the importance that employers give to so-called non-cognitive skills – such as persistence, reliability and self-discipline – as well as raising questions for policy-oriented research on the role of education systems, and particularly early childhood education, in developing and signalling such skills (see the Definitions and methodologies section below).

**Box A9.1. Variations in earnings by disciplines – the example of Canada**

Though indicators present a single estimate for returns to a particular level of education, the variations and explanations behind such indicators are great. This box explores these variations for Canada. Data from three different cohorts of tertiary-type B graduates (1990, 1995 and 2000, along with earnings two years after graduation) suggest that earnings vary by discipline as well as by gender. The chart below shows that median earnings in 2002 (in 1997 constant Canadian dollars) for graduates from 2000 can be as high as \$32 911 for male health graduates and as low \$22 604 for women graduates of education. By reviewing the earnings of three different cohorts of graduates, the impact of labour market demands over a ten-year period can be shown. Gains over the period were evident for men and women who were graduates in fine arts, but they had the lowest median earnings. Those with degrees in health fields lost ground, however, although they had higher earnings than most other graduates. In general, women graduates earn slightly less compared to men with degrees in the same discipline.

**Median earnings for three cohorts of tertiary-type B male and female graduates by discipline (1990, 1995, 2000)**

Source: Drewes, Torben (2006), *Returns to College Education: Evidence from the 1990, 1995, and 2000 National Graduates Surveys*, Learning Research Series, Human Resources and Social Development Canada.

Information on variation in earnings by disciplines is important information for students and other stakeholders, as well as an essential way of analysing how different disciplinary fields contribute to the economy. Similarly, accessing data over time on earnings by levels of education provides further information about the match between supply and demand. In addition, the analytical possibilities and the policy implications that can be drawn from trend data by fields of study are substantial. International comparable data would provide additional analytical potentials by connecting country specific and global trends. The Canadian illustration thus serves as an example to strive for in international data collections.

### Rates of return to investment in education

The impact of education on earnings can be evaluated in the framework of investment analysis in which an individual incurs costs of getting an education (direct costs such as tuition while in school and indirect costs such as foregone earnings while in school). The effectiveness of this investment can be assessed by estimating the economic rate of return to the investment, which measures the degree to which the costs of attaining higher levels of education are translated into higher levels of earnings. The measure of return used here is the internal rate of return, which is effectively an interest rate that measures the economic return to an investment. This rate equates the costs required to attain the next highest level of education with the present value of a lifetime stream of additional earnings associated with the higher level of attainment. This indicator is analysed from two different points of view: rates of return to the individual (Tables A9.5 and A9.6), which reflect only the individual's earnings and costs, and rates of return to government (Tables A9.7 and A9.8). The return to government includes higher income tax and social contributions collected, as well as costs borne by the government. These private and public returns are calculated for 11 OECD countries.

Internal rates of return are computed for the attainment of two different levels of education: upper secondary education or post-secondary non-tertiary education, following from a lower secondary level of attainment (Tables A9.5 and A9.7); and tertiary education, following from an upper secondary or post-secondary non-tertiary level of educational attainment (Tables A9.6 and A9.8). Unlike the results presented in *Education at a Glance 2006* (OECD, 2006a), this year this indicator presents internal rates of return for obtaining upper secondary education or post-secondary non-tertiary education, following from a lower secondary level of attainment and based on the assumption that foregone earnings are fixed at the level of the minimum wage (when no national minimum wage was available, the wage was selected among wages determined in collective agreements). This implies that while in school obtaining an upper secondary level of education, the individual receives no earnings, compared with an individual at lower secondary level of education who receives the minimum wage or equivalent.

Internal rates of return are computed for two different periods in the individual's lifetime: immediately following initial education, and at the age of 40. In the latter, forgone earnings depends upon average earnings at the lower level of education and social benefits varying across countries.

In addition, when calculating the internal rate of return at the age of 40, the analysis explores the impact on rates of return – for individuals and government – of the costs of education.

All results are presented separately for males and females.

#### *Private internal rates of return to investment in education*

The private internal rate of return for the individual is estimated on the basis of the additions to after-tax earnings that result from a higher level of educational attainment, net of the additional private costs (private expenditures and foregone earnings) that attaining this higher level of education requires. In general, the living expenses of students (cost of housing, meals, clothing, recreation, etc.) are excluded from these private expenditures.

Estimates of private rates of return for an individual who has invested in obtaining upper secondary or post-secondary non-tertiary education from an original lower secondary level of

education are presented in Table A9.5. Estimates for an individual who has invested in obtaining a tertiary-level education, up to the attainment of an advanced research qualification starting from an upper secondary level of education are presented in Table A9.6.

Private rates of return were calculated for the following two scenarios:

1. The individual has continued directly to the next highest level of education before entering the labour market.
2. Attaining the next highest level of education has been postponed until the age of 40, when education is resumed on a full-time basis. Two cases are examined in this scenario: *i*) the individual bears the direct costs of tuition (as reported by national education authorities) and foregoes earnings (net of taxes) while studying; and *ii*) the individual bears no direct tuition costs, but again bears the cost of foregoing earnings.

The results show that for males, in all countries except Hungary, Norway and Switzerland, the rates of return to the attainment of upper secondary or post-secondary non-tertiary education exceed those for tertiary education.

At the upper secondary level, the private internal rate of return shows greater variability than at tertiary level, while the former varies from 4.6 to 24%, the latter is not below 8% (Table A9.5, A9.6). Private rates of return at the upper secondary level are seen to be higher for females than males in two countries: Hungary and New Zealand, and in five countries at the tertiary level: Belgium, Korea, New Zealand, Norway and the United Kingdom.

The results also show that when an individual attains the next higher level of education at age 40, private rates of return to tertiary education are generally higher than those for the achievement of upper secondary education, except in Denmark, New Zealand and the United States. At the tertiary level, the additional incentive created by eliminating tuition costs tends to be weak. At the upper secondary level, eliminating tuition costs results on average in 0.4 of a percentage point increase in the private rate of return for males and a 1.0 percentage point increase for females. At the tertiary level, eliminating tuition costs increases the private rate of return by 0.9 percentage points for males and 1.7 percentage points for females. Nevertheless, while in countries such as Denmark, Finland and Norway the impact on private rates of return from eliminating the student's tertiary-level tuition costs is small, the impact is significantly larger in Belgium, Hungary, Korea, the United Kingdom and the United States.

### ***Public internal rates of return to investment in education***

The public internal rate of return is one way of examining the effect on public-sector accounts of individuals' choices to invest in education and the effect of the different policy settings that affect these investments. For the public sector, the costs of education include direct expenditures on educational institutions (such as direct payment of teachers' salaries, direct payments for the construction of school buildings, and buying textbooks, etc.) and public private transfers (such as public subsidies to households for scholarships and other grants and to other private entities for the provision of training at the workplace, etc.). The public costs of education also include income tax revenues on students' foregone earnings. The benefits include increased revenues from income taxes on higher wages, plus social insurance payments. In practice, the achievement of higher levels of education will give rise to a complex set of fiscal effects on the benefit side, beyond the effects of

wage and government payments-based revenue growth. For instance, better educated individuals generally experience superior health status, lowering public expenditure on the provision of health care. And, for some individuals, achieving higher levels of educational attainment may lower the likelihood of committing certain types of crime (see Indicator A10 in *Education at a Glance 2006*); this in turn reduces public expenditure. However, tax and expenditure data on such indirect effects of education are not readily available for inclusion in these rate-of-return calculations.

Estimates of public rates of return are shown in Tables A9.7 and A9.8. Table A9.7 presents public rates of return for an individual who has invested in obtaining upper secondary or post-secondary non-tertiary education (ISCED level 3/4), from an original lower secondary level of education. This estimate depends on the same assumption made for the private rate of return, *i.e.* an individual with a lower secondary level of education who earns the minimum wage or equivalent. Table A9.8 concerns an individual who has invested in obtaining a tertiary-level education, up to the attainment of an advanced research qualification (ISCED level 5(A, B)/6), starting from an upper secondary or post-secondary non-tertiary level of education (ISCED level 3/4).

As with the estimation of private rates of return, the calculation considered two scenarios:

1. Following initial education, the individual has continued directly to the next highest level of education, before entering the labour market.
2. Attaining the next highest level of education has been postponed until the age of 40, when education is resumed on a full-time basis. Two cases are examined in this scenario: *i)* the individual bears the direct costs of tuition (as reported by national education authorities) and foregoes earnings (net of taxes) while studying; and *ii)* the individual bears no direct tuition costs, but again bears the cost of foregoing earnings.

The results show that, for the achievement of the tertiary level of attainment during initial education, the public rate of return is in all cases lower than the private rate of return (except for Belgium, Korea and, for males, New Zealand). When the individual goes back to full-time education in mid-career, and bears the direct costs of tuition and foregone earnings, public rates of return for completing tertiary education are lower than private rates of return in all countries (Table A9.8). These low rates are driven by a number of factors including the high costs of providing education and high losses in tax receipts (when the individual in study foregoes earnings) relative to tax revenues (when the individual returns to work).

The results show that, for upper secondary education, the effect of the public sector bearing the individual's tuition costs is to lower the public rate of return by an average of 0.2 percentage points for males and 0.3 percentage points for females (Table A9.7). At the tertiary level, the average effect is to lower the public rate of return by about 0.7 of a percentage point for males and 1 percentage point for females. The magnitude of this decline in the public rate of return in the United States is noteworthy – 2.3 percentage points for males and 2.8 percentage points for females (Table A9.8) – which is partially explained by the high private contributions to the costs of tertiary education in the United States.

### ***The interpretation of internal rates of return***

For those who acquire upper secondary or tertiary education, high private internal rates of return in most countries (though not in all) indicate that human capital investment appears

to be an attractive way for the average person to build wealth. Furthermore, and with some exceptions, policies that reduce or eliminate the direct costs of education are seen to have only a modest impact on individuals' decisions to invest in mid-career learning.

In many cases, the reported private internal rates of return are above – and in a number of countries significantly above – the risk-free real interest rate, which is typically measured with reference to rates applying on long-term government bonds. However, returns on human capital accumulation are not risk-free, as indicated by the wide distribution of earnings among the better educated. Moreover, not everyone who invests in a course of education actually completes the course. Rates of return will be low, and possibly negative, for individuals who drop out. Therefore, individuals contemplating an investment in education are likely to require a compensating risk premium. However, in a number of countries, the size of the premium of the internal rates of return over the real interest rate is higher than would seem to be warranted by considerations of risk alone. If returns to this form of investment are high, relative to investments of similar risk, there is some obstacle to individuals making the investment. High risk-adjusted private rates of return provide initial grounds for policy intervention to alleviate the relevant constraints.

For one, high rates of return indicate a shortage of better-educated workers, driving up earnings for these workers. Such a situation might be temporary, with high returns to education eventually generating enough supply response to push the rates into line with returns to other productive assets. However, the speed of adjustment would depend largely on the capacity of the education system to respond to the derived increase in demand and the capacity of the labour market to absorb the changing relative supplies of labour. The rebalancing mechanism could be accelerated by making better information about the returns to different courses of study available to students, helping them to make more informed choices.

Part of the high returns may also be compatible with market stability. According to this interpretation, the high internal rates of return would partly reflect economic rents on a scarce resource, namely ability and motivation. If the returns to education at the margin are lower, the case for public intervention to stimulate human capital accumulation is lessened if the quality of the marginal student cannot be improved. However, to the extent that the education system can improve both cognitive and non-cognitive skills of young people, education policy can make a significant contribution to efficiency and equity in the long run. The results from the OECD Programme for International Student Assessment (PISA) suggest that some countries succeed much better than others in securing high and equitable educational performances at the age of 15 years.

Internal rates of return to investment in education can also be viewed from a societal perspective. Such a perspective would combine both the private and public costs and benefits of additional education. For instance, the social cost of education would include foregone production of output during study periods as well as the full cost of providing education, rather than just the cost borne by the individual. A social rate of return should also include a range of possible indirect benefits of education, which also have economic repercussions, such as better health, more social cohesion and more informed and effective citizens. While data on social costs are available for most OECD countries, information on the full range of social benefits is less readily available. Indeed, for a number of possible external factors associated with education, current understanding of the nature and size of the effects is incomplete.

## A9

It is important to consider some of the broad conceptual limitations to estimating internal rates of return in the manner done here:

- The data reported are accounting rates of return only. The results would no doubt differ from econometric estimates that would rely, for example, on an earnings function approach, rather than on a lifetime stream of earnings derived from average empirical earnings.
- Estimates relate to levels of formal educational attainment only. They do not reflect the effects of learning outside of formal education.
- The approach used here estimates future earnings for individuals with different levels of educational attainment based on knowledge of how average gross earnings in the present vary by level of attainment and age. However, the relationship between different levels of educational attainment and earnings may not be the same in the future as it is today. Technological, economic and social change could all alter how wage levels relate to the level of educational attainment.
- As with the discussion of the interpretation of earnings dispersion data, differences in internal rates of return across countries in part reflect different institutional and non-market conditions that bear on earnings. Institutional settings that limit flexibility in relative earnings are a case in point.
- Estimates are based on average pre-tax earnings for persons at different levels of educational attainment. However, at a given level of educational attainment, individuals who have chosen different courses of study or who come from different social groups may register different rates of return.
- In estimating benefits, the effect of education in increasing the likelihood of employment is taken into account. However, this also makes the estimate sensitive to the stage in the economic cycle when the data were collected.

The rate-of-return calculations also involve a number of restrictive assumptions necessary for international comparability. In particular, it was not possible to include the effects on public accounts of changes in social transfer payments resulting from changes in wages. This is largely because the rules that govern eligibility for a broad range of social entitlements vary greatly across countries as well as by marital or civic status (and sometimes other criteria). Consequently, to ensure comparability, the rates of return have been calculated on the assumption that the individual in question is single and childless.

The above analyses could be extended in a number of ways, subject to data availability. In particular, more differentiated and comparable data relative to costs per student and a range of social transfer payments would be useful. Estimating changes in value added tax receipts resulting from the increased earnings acquired through obtaining higher levels of education would also contribute to a more complete assessment of impact on public accounts. The calculations do not consider that those with high earnings can often generate higher levels of income after age 64 as a consequence of their having superior pension arrangements.

### Definitions and methodologies

Earnings data in Table A9.1a are based on an annual reference period in Austria, Canada, the Czech Republic, Denmark, Finland, Ireland, Italy, Korea, Luxembourg, Norway, Portugal, Spain, Sweden, Turkey and the United States. Earnings are reported weekly in Australia, New Zealand and the United Kingdom, and monthly in Belgium, France, Germany, Hungary, Poland and

Switzerland, and the partner economy Israel. Data on earnings are before income tax, while earnings for Belgium, Korea and Turkey are net of income tax. Data on earnings for individuals in part-time work are excluded for the Czech Republic, Hungary, Luxembourg and Poland, while data on part-year earnings are excluded for Hungary, Luxembourg and Poland.

The research regarding earnings determination in the United States is described in Bowles and Gintis (2000).

Earnings assumptions were made in calculating rates of return.

For the individual who decides to attain upper secondary education as part of his or her original education, the assumptions concerned the estimated level of foregone earnings fixed at the minimum wage (when no national minimum wage was available, the wage has been selected among wages determined in collective agreements). This assumption aims at counterbalancing the excessively low recorded earnings for 15-to-24-year-olds with lower secondary education, which caused excessively high estimates in earlier editions of *Education at a Glance*.

For the individual who decides to return to education in mid-career, the assumptions concerned the immediate earnings increase (10% relative to the level of earnings at the previous level of educational attainment) and the time required for convergence with the average wage of individuals already holding the next highest level of educational qualification (two years). These assumptions are somewhat *ad hoc*. Empirical evidence on the earnings of adults who return to work following part-time or full-time studies is scarce, especially for individuals attaining an upper secondary qualification. However, Canadian data indicate a convergence period of just two years for 30-to-49-year-olds who obtain a university degree, with a still shorter catch-up time for those who obtain a tertiary degree. It should be noted, nevertheless, that the Canadian data are derived from a small sample of individuals and do not control for the fact that those who invested in education may differ in important ways – such as motivation and inherent ability – by comparison with those who did not.

For the methods employed for the calculation of the rates of return in Tables A9.5 to A9.8, see Annex 3 at [www.oecd.org/edu/eag2007](http://www.oecd.org/edu/eag2007).

Table A9.1a. (continued)

**Relative earnings of the population with income from employment (2005 or latest available year)**

By level of educational attainment and gender for 25-to-64-year-olds and 30-to-44-year-olds (upper secondary and post-secondary non-tertiary education = 100)

|                 |      |       | Below upper secondary education |       | Post-secondary non-tertiary education |       | Tertiary-type B education |       | Tertiary-type A and advanced research programmes |       | All tertiary education |       |
|-----------------|------|-------|---------------------------------|-------|---------------------------------------|-------|---------------------------|-------|--|-------|------------------------|-------|

# READER'S GUIDE

## **Coverage of the statistics**

Although a lack of data still limits the scope of the indicators in many countries, the coverage extends, in principle, to the entire national education system (within the national territory) regardless of the ownership or sponsorship of the institutions concerned and regardless of education delivery mechanisms. With one exception described below, all types of students and all age groups are meant to be included: children (including students with special needs), adults, nationals, foreigners, as well as students in open distance learning, in special education programmes or in educational programmes organised by ministries other than the Ministry of Education, provided the main aim of the programme is the educational development of the individual. However, vocational and technical training in the workplace, with the exception of combined school and work-based programmes that are explicitly deemed to be parts of the education system, is not included in the basic education expenditure and enrolment data.

Educational activities classified as “adult” or “non-regular” are covered, provided that the activities involve studies or have a subject matter content similar to “regular” education studies or that the underlying programmes lead to potential qualifications similar to corresponding regular educational programmes. Courses for adults that are primarily for general interest, personal enrichment, leisure or recreation are excluded.

## **Calculation of international means**

For many indicators an OECD average is presented and for some an OECD total.

The OECD average is calculated as the unweighted mean of the data values of all OECD countries for which data are available or can be estimated. The OECD average therefore refers to an average of data values at the level of the national systems and can be used to answer the question of how an indicator value for a given country compares with the value for a typical or average country. It does not take into account the absolute size of the education system in each country.

The OECD total is calculated as a weighted mean of the data values of all OECD countries for which data are available or can be estimated. It reflects the value for a given indicator when the OECD area is considered as a whole. This approach is taken for the purpose of comparing, for example, expenditure charts for individual countries with those of the entire OECD area for which valid data are available, with this area considered as a single entity.

Note that both the OECD average and the OECD total can be significantly affected by missing data. Given the relatively small number of countries, no statistical methods are used to compensate for this. In cases where a category is not applicable (code “a”) in a country or where the data value is negligible (code “n”) for the corresponding calculation, the value zero is imputed for the purpose of calculating OECD averages. In cases where both the numerator and the denominator of a ratio are not applicable (code “a”) for a certain country, this country is not included in the OECD average.

For financial tables using 1995 data, both the OECD average and OECD total are calculated for countries providing both 1995 and 2004 data. This allows comparison of the OECD average and OECD total over time with no distortion due to the exclusion of certain countries in the different years.

For many indicators an EU19 average is also presented. It is calculated as the unweighted mean of the data values of the 19 OECD countries that are members of the European Union for which data are available or can be estimated. These 19 countries are Austria, Belgium, the Czech Republic, Denmark, Finland, France, Germany, Greece, Hungary, Italy, Ireland, Luxembourg, the Netherlands, Poland, Portugal, the Slovak Republic, Spain, Sweden and the United Kingdom.

### ■ **Classification of levels of education**

The classification of the levels of education is based on the revised International Standard Classification of Education (ISCED-97). The biggest change between the revised ISCED and the former ISCED (ISCED-76) is the introduction of a multi-dimensional classification framework, allowing for the alignment of the educational content of programmes using multiple classification criteria. ISCED is an instrument for compiling statistics on education internationally and distinguishes among six levels of education. The glossary available at [www.oecd.org/edu/eag2007](http://www.oecd.org/edu/eag2007) describes in detail the ISCED levels of education, and Annex 1 shows corresponding typical graduation ages of the main educational programmes by ISCED level.

### ■ **Symbols for missing data**

Six symbols are employed in the tables and charts to denote missing data:

- a* Data is not applicable because the category does not apply.
- c* There are too few observations to provide reliable estimates (*i.e.* there are fewer than 3% of students for this cell or too few schools for valid inferences). However, these statistics were included in the calculation of cross-country averages.
- m* Data is not available.
- n* Magnitude is either negligible or zero.
- w* Data has been withdrawn at the request of the country concerned.
- x* Data included in another category or column of the table (*e.g.* *x*(2) means that data are included in column 2 of the table).
- ~ Average is not comparable with other levels of education.

### ■ **Further resources**

The website [www.oecd.org/edu/eag2007](http://www.oecd.org/edu/eag2007) provides a rich source of information on the methods employed for the calculation of the indicators, the interpretation of the indicators in the respective national contexts and the data sources involved. The website also provides access to the data underlying the indicators as well as to a comprehensive glossary for technical terms used in this publication.

Any post-production changes to this publication are listed at [www.oecd.org/edu/eag2007](http://www.oecd.org/edu/eag2007).

The website [www.pisa.oecd.org](http://www.pisa.oecd.org) provides information on the OECD Programme for International Student Assessment (PISA), on which many of the indicators in this publication draw.

*Education at a Glance* uses the OECD's StatLinks service. Below each table and chart in *Education at a Glance 2007* is a url which leads to a corresponding Excel workbook containing the underlying data for the indicator. These urls are stable and will remain unchanged over time. In addition, readers of the *Education at a Glance* e-book will be able to click directly on these links and the workbook will open in a separate window.

### Codes used for territorial entities

These codes are used in certain charts. Country or territorial entity names are used in the text. Note that in the text the Flemish Community of Belgium is referred to as "Belgium (Fl.," and the French Community of Belgium as "Belgium (Fr.)."
